

NAVlib Overview

 support.oxts.com/hc/en-us/articles/360000240889-NAVlib-Overview

What is NAVlib?

NAVlib is a .NET API developed by OxTS to allow communication with OxTS products and processing of stream data both from live devices and previously logged files. It consists of libraries:

OxTS.NavLib.LowLevel - This is the basic link to the low-level C++ functionality. It is not recommended to use this dll directly.

OxTS.NavLib.Core – The main functionality of NAVlib including the datastore manager classes.

There are also extension libraries such as those required for creating plugins for OxTS applications.

[Click here to be taken to the full NAVlib manual.](#)

What can be done using NAVlib?

NAVlib can be used to create standalone applications or plugins for OxTS applications. All of the OxTS applications included in the NAVsuite use the NAVlib API to connect and communicate with OxTS hardware. The main functions of NAVlib are to:

- Get available devices on the network or over a serial connection. (NAVdisplay/NAVbase/NAVconfig/NAVsolve)
- Get measurements from available devices. (NAVdisplay/NAVbase/NAVconfig)
- Load processed files to get streams/ measurements. (NAVgraph/NAVsolve)
- Send commands directly to a device. (NAVdisplay)

What license does NAVlib use?

NAVlib uses a custom license file that must be built into the application using the NAVlib dlls. Please contact OxTS if you wish to request a license.

What does NAVlib not do?

NAVlib does not currently have an FTP interface to the devices. This means that this must be done separately if the user wishes to set up the device with new config files (like in NAVconfig).

What measurements are available through NAVlib?

See the Measurement documentation for more information on the measurements available.

Can I use NAVlib on Linux?

No, NAVlib is designed to be used in Windows and uses low level Windows functionality for opening ports and threading, there is currently no plans for a Linux release.
